Whisper Notes

React Project Scaffold — Milestone 3

Frontend Systems · SoSe 2026 · Prof. Dr. Peter Braun

Mahmut Ekrem Acar Orhan Bolat Erdil Kunt Taylan Yildirim

Whisper Notes is a React frontend application for turning audio recordings into organised, shareable notes. This milestone delivers the technical foundation: a working Vite-based scaffold, a meaningful folder structure, React Router navigation, and first placeholder components for the four main views. The repository also contains a `README.md` with setup instructions.

Project Structure

The project is organised as follows:

```
whisper-notes/
+-- src/
|   +-- assets/          # Static assets (placeholder, .gitkeep)
|   +-- components/
|   |   +-- Navigation.jsx   # Top navigation bar
|   +-- pages/
|   |   +-- Login.jsx        # Entry point -- authentication form
|   |   +-- Transcribe.jsx   # Core view -- audio upload workflow
|   |   +-- Results.jsx      # Displays transcription output
|   |   +-- SharedFiles.jsx  # Lists past transcriptions
|   +-- services/        # Future API integration (placeholder, .gitkeep)
|   +-- styles/
|   |   +-- global.css   # Shared styles and design tokens
|   +-- App.jsx          # Root component with navigation state
|   +-- main.jsx         # React entry point
+-- index.html
+-- package.json
+-- package-lock.json
+-- vite.config.js
+-- README.md
```

This structure separates reusable components, page views, styling, and future service logic. The `services/` directory is reserved for API and backend integration code to be added in later milestones.

Implemented Components and Views

The current scaffold includes a navigation component and four initial page components:

- **Navigation**: Provides visible navigation between the main sections of the application.
- **Login**: Placeholder view for future user authentication or access flow.
- **Transcribe**: Placeholder view for the planned audio upload or recording workflow.
- **Results**: Placeholder view for reviewing transcription results.
- **Shared Files**: Placeholder view for files shared with or by the user.

Navigation is currently handled inside React using component state. This is sufficient for the first scaffold and keeps the implementation simple while the main screens are still being shaped.

Technical Decisions

The project was initialized with Vite because it provides a lightweight and fast development setup for React applications. React is used for the frontend implementation, as required by the portfolio assignment.

At this stage, the application does not yet use a full routing library such as React Router. Instead,

the root component stores the active page in local state and renders the selected page component. This keeps the scaffold understandable and easy to modify. A routing library can be introduced later if URL-based navigation becomes necessary.

The CSS is currently placed in a global stylesheet. This is acceptable for the early scaffold and allows shared layout, navigation, and page styling to be defined in one place. As the project grows, styles can be split into component-specific files or another styling approach if needed.

Current Limitations and Next Steps

The current version is a technical scaffold, not yet a complete prototype. The main views are present, but their functionality is still limited to placeholder content.

The next steps are:

- add real form elements for login and audio upload,
- implement initial user interaction in the transcription workflow,
- connect the pages into a more realistic application flow,
- improve styling based on the design draft,
- prepare mock data or a service layer for later backend/API integration,
- decide whether React Router is needed for URL-based navigation.

AI Acknowledgement

This document and parts of the initial frontend code were prepared with support from ChatGPT and Claude. All project decisions and submitted content were reviewed and understood by the team.
